**Materialise**

My Solution > Server Status > Performance History tab.

- This screen let the user chart the hardware performance of the servers running the Solution's eTools components
- User can select the time horizon from predefined values (1 hour is the default) or specify a custom time period
- Even though the Performance History and Log window opens from the Server Status tab of a specific server, it gives the user access to performance history and log for all servers in the solution. This is done so that the user doesn't have to "jump" around the application to see and compare performance history across servers.

My Solution > Server Status > Performance Log tab.

- Performance log tab lets user generate a log file containing performance metrics for servers in the solution. Exact requirements for this component are still unknown. At this point in the design lifecycle of this screen the user can select the time horizon, press the "generate log" button, and save the generated file somewhere locally via the browser's standard "Save As…" dialog.
